Air Quality Policy

Michael Gauss

Norwegian Meteorological Institute, Oslo, Norway

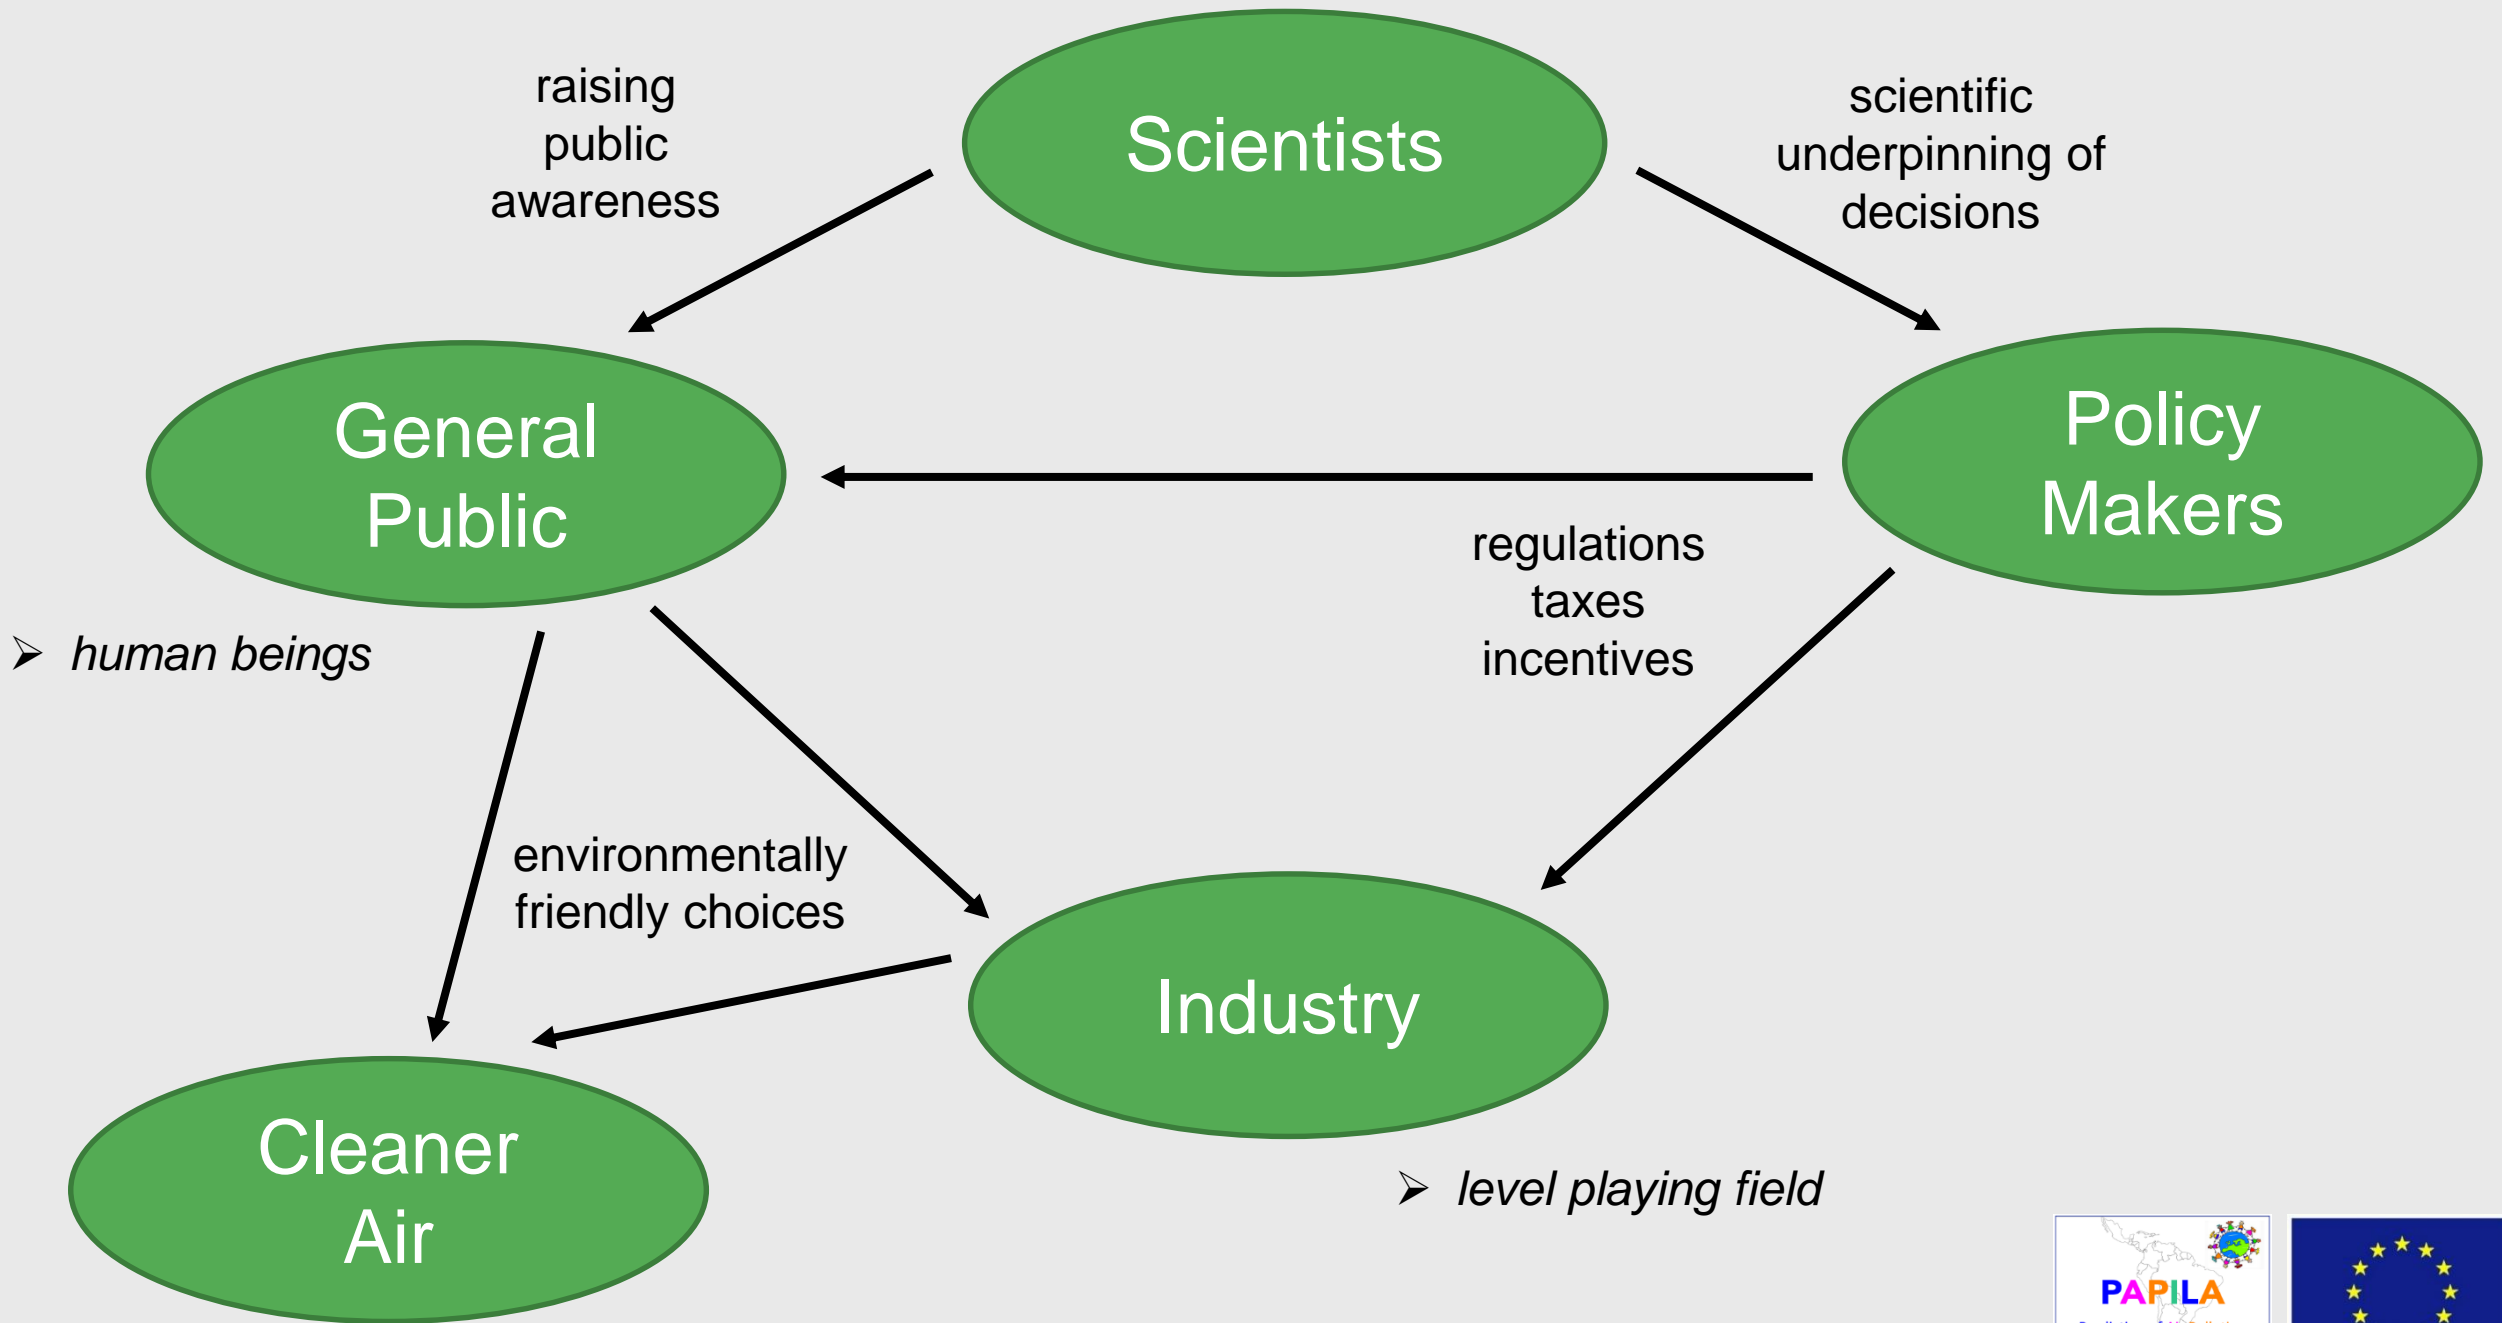

Prologue

- The topic of air quality related legislation is broad!
- I will focus here only on policy aspects that can be supported by air pollution modelling / forecasting

Outline of presentation

- What can scientists do for air quality policy?
- A few examples of modelling products for policy support
- An example of a regulation: Air Quality Standards

Air Quality Policy

- **International** air quality agreements (UN ECE LRTAP Convention, EU Air Quality Directive, US-Canada Air Quality Agreement, etc.)
- **National** air quality legislation (varies a lot from country to country)
- Legislation also (and sometimes *only*) exists at **province or municipality** level, or even smaller administrative divisions.
- Main ‘ingredients’:
Regulation – Monitoring - Enforcement

Approaching air quality policy makers

- Who are they? (exercise: find out for your country or municipality!)
- What do they need from you?
 - find out about their tasks
 - find out how you can help them fulfill their tasks
- We need to provide them with evidence in a clear and understandable manner
 - to help decision makers ‘higher up’ find the best trade-offs

Some fundamental questions of AQ policy

- What are the levels of air pollution?
 - Measure/model variability in space and time
 - Assess the impacts of air pollution
 - Support alerts and compliance reporting
- Where does air pollution come from?
 - Natural vs. anthropogenic sources (relevant for assessing compliance)
 - Different activities / industry sectors (who/what are the main contributors to air pollution?)
 - Indigenous vs. imported air pollution (will local measures be helpful?)
- What can we do about it? (exercise: make a list of mitigation measures!)
 - Suggest short-term measures
 - Suggest long-term measures
 - Support air quality planning
(assess the effectiveness of policies in the past and the future)

Why use a model?

- spatial coverage
- relatively cheap once established
- always on
- forecast capability
- fast enough to support short-term mitigation
- ... but be aware of the uncertainties!

Air Quality Standards (AQS) and Air Quality Indices (AQI)

- **Air quality standards** set limit values on *pollutant concentrations* in ambient air, which should not (or must) not be exceeded
- **Air quality indices** are a means to assess and *communicate* air pollution more efficiently
- **Different standards and indices are used in different countries**
 - AQS and AQI need to take local circumstances into account

From AQ guidelines to AQ standards, e.g. particulate matter

		WHO guideline	EU Limit / Target	US Primary / Secondary	Chile Short-term standard / Alert level
Annual mean ($\mu\text{g}/\text{m}^3$)	PM_{2.5}	10	25 / 25	12 / 15	- / -
	PM₁₀	20	40 / -	- / -	- / -
24-hour mean ($\mu\text{g}/\text{m}^3$)	PM_{2.5}	25	- / -	35 / 35	50 / 80-109
	PM₁₀	50	50 / -	150 / 150	150 / 195-239

Standards can have different criteria for how many times they may be exceeded

(e.g. EU limit for 24-hr PM₁₀ not to be exceeded more than 35 times in a calendar year;

US limit for 24-hr PM₁₀ not to be exceeded more than once a year, etc.)

(Exercise: find out for your country and for other species!)

Air Quality Standards – which species/limits?

- The species should be measurable (for enforcement)
 - The limit value should be related to its impacts (see, e.g. WHO)
 - The limit value should be attainable (i.e. not be too low)
 - The limit value should evoke improvement (i.e. not be too high)
- Best choices for limit values differ from country to country and can change over time...

Conclusions and recommendations

- Policy makers need clear and relevant information from scientists for monitoring air quality and for designing and implementing regulations and abatement measures;
- Air quality policy is about finding best compromises between the effectiveness of measures, their feasibility and cost, and the possibility of monitoring and enforcement.
- **A strong science-policy interface is a win-win**
- *PAPILA* aims to integrate measurements and modelling capabilities into near-real-time assessment and forecasts of air quality also to assist policy makers;
- Regional services become even more useful when being downscaled, at least in strongly polluted/populated areas.
